JavaScript: Coercion and Functions

Lecture 23

Conversion of Primitives: Numbers

		string	number	boolean
numbers	`0`	`"0"`		`false`
	`-0`	`"0"`		`false`
	`1`	`"1"`		`true`
	`NaN`	`"NaN"`		`false`
	`Infinity`	`"Infinity"`		`true`
	`-Infinity`	`"-Infinity"`		`true`
	`6.022e23`	`"6.022e+23"`		`true`

Conversion of Primitives: Boolean, Strings

		string	number	boolean
boolean	`true`	`"true"`	`1`	
	`false`	`"false"`	`0`	
strings	`""`		`0`	`false`
	`"  "`		`0`	`true`
	`"1.2"`		`1.2`	`true`
	`"0"`		`0`	`true`
	`"one"`		`NaN`	`true`

Conversion of Primitives: Undefined, Null

		string	number	boolean
undefined	`undefined`	`"undefined"`	`NaN`	`false`
null	`null`	`"null"`	`0`	`false`

Summary of (Simple?) Rules

- How do numbers convert to…?
  - Boolean: 0 is false, everything else is true (exception: NaN is also 0)
- How do strings convert to…?
  - Numbers: non-valid syntax is NaN (exception: empty/blank string is 0)
  - Boolean: empty string is false, everything else is true
- How does undefined convert to…?
  - Number: NaN
- How does null convert to…?
  - Number: 0

Alternative: Column-Major View (Booleans)

- How do things convert to boolean?
  - Empty string is **`false`**
  - Numbers **`(+/-)0`** and **`NaN`** are **`false`**
  - **`undefined`** and **`null`** are **`false`**
- Aka "falsy" (vs. "truthy")
- Importance: Used in Boolean contexts

```
if (pet)… // evaluate pet as a boolean
```

- Pitfall: &&, || may not result in a boolean
  - **`x || y`** means **`x ? x : y`** (first evaluate x as a boolean)

```
p = "cat" || "dog"      //=> p == "cat"
```

  - Old idiom: **`!!x`** forces conversion to boolean

```
p = !!("cat" || "dog") //=> p == true
```

Alternative: Column-Major View (Numbers)

- How do things convert to Numbers?
  - Empty (and whitespace) string is `0`
  - Non-numeric strings are **`NaN`**
  - **`undefined`** is **`NaN`**
  - **`null`** is `0`
- Importance: Used in evaluation of ==

== Evaluation is… Different

- When types do not match, coerce:
  - **`null`** & **`undefined`** are equal to each other (and nothing else)
  - Strings & booleans are converted to *numbers*

```
"1.0" == true && "" == false // ie 1 == 1 && 0 == 0
"   " == false               // but "   " is truthy!
```

  - Pitfall: **`NaN`** is *not equal* to **`NaN`**
- When *one* operand is an object:
  - Convert via **`valueOf`** (fall back **`toString`**)
  - Result then compared with usual **`==`** rules
  - Note: no coercion when *both* operands are references (**`==`** means reference equality)
- Sanity:
  - Use `===` since it never coerces

Your Turn

Evaluate: True or false?

```
true == '1'

'false' == false

0 == '0'

0 == ''

NaN == NaN
```

Surprising Consequences

```
false == 'false'
false == '0'
!!'0'
('0' == 0) && (0 == '') && ('0' != '')

(NaN == true) || (NaN == false)
!!NaN
(NaN != 0) && (!!NaN == !!0)
```

- dorey.github.io/JavaScript-Equality-Table

Functions are People too

- Named functions: declaration & use

```
function foo(a, b) { … }
foo("hi", 3);
```

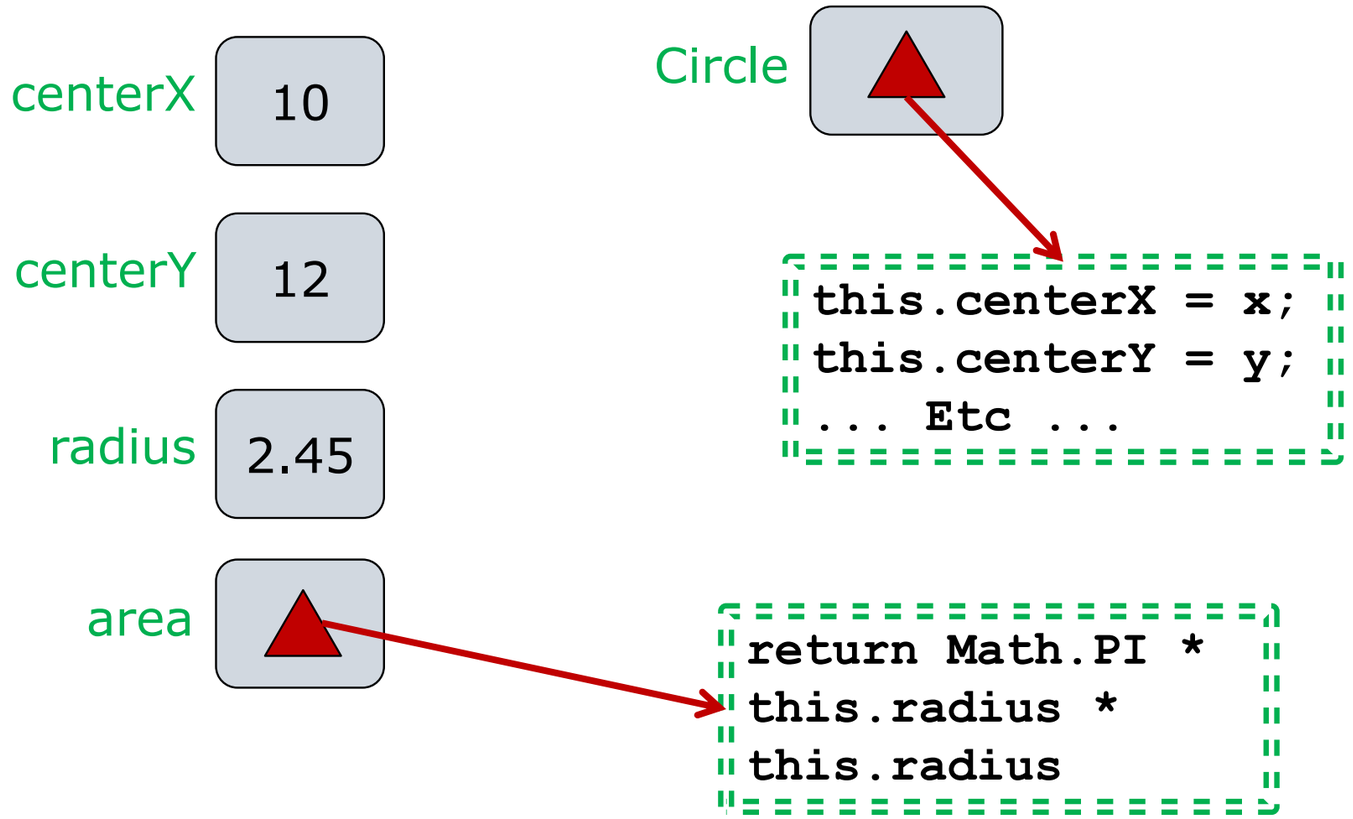
- Anonymous functions

```
function(a, b) { … }
// how is such a thing invoked?
```

- Functions are objects (first-class citizens)
- They can be assigned to variables!

```
let foo = function(a, b) { … };
foo("hi", 3);
let bar = foo;  // cf. let bar = foo();
bar("world", 17);
```

Functions are Objects



Functions Can Be Arguments

```
function apply(f, a) {
  return f(a); // f is a function!
}

function square(i) {
  return i * i;
}

square(3);           //=> 9
apply(square, 5);    //=> 25
apply(square, 12); //=> 144
```

Functions Can Be Return Values

```
function grantDegree() {

  function addTitle(name) {
    return `Dr. ${name}`; // string interpolation
  }
  return addTitle;          // returns a function!
}

let phd = grantDegree();  // phd is a function
phd("Turing");            // function call
phd(3/2);                 //=> "Dr. 1.5"
```

Closures

```
function greaterThanZero() {
  let bound = 0
  function compare(value) {
    return value > bound;
  }
  return compare; // 1-arg function
}

let testPos = greaterThanZero();
testPos(4)          //=> true
testPos(-3)         //=> false
```

Closures + Parameters

```
function greaterThan(bound) {

  function compare(value) {
    return value > bound;
  }
  return compare; // 1-arg function
}

let testPos = greaterThan(0);
testPos(4)          //=> true
testPos(-3)         //=> false
```

Closures + Anonymity

```
function greaterThan(bound) {

  function compare(value) {
    return value > bound;
  }
  return compare; // 1-arg function
}

let testPos = greaterThan(0);
testPos(4)          //=> true
testPos(-3)         //=> false
```

Closures + Anonymity (2)

```
function greaterThan(bound) {

  let compare = function(value) {
    return value > bound;
  }
  return compare; // 1-arg function
}

let testPos = greaterThan(0);
testPos(4)          //=> true
testPos(-3)         //=> false
```

Closures + Anonymity (3)

```
function greaterThan(bound) {

  return function(value) {
    return value > bound;
  }
}

let testPos = greaterThan(0);
testPos(4)          //=> true
testPos(-3)         //=> false
```

Arrow Function Expressions

- Concise notation for anonymous functions
- Syntax:
  - Omit **`function`** keyword
  - Place arrow (=>) between the parameter list and the body
  - **`(a, b = 10) => { ... }`**

```
(r) => { return Math.PI * r**2 }
```

- Shortcut for one-liner: omit **`return`** and **`{}`** ’s

```
(r) => Math.PI * r**2
```

- Shortcut for one parameter: omit () ’s

```
r => Math.PI * r**2
```

- Use where a function expression is needed

```
let area = r => Math.PI * r**2
```

Closures + Anonymity (4)

```
function greaterThan(bound) {

  return function(value) {
    return value > bound;
  }
}

let testPos = greaterThan(0);
testPos(4)          //=> true
testPos(-3)         //=> false
```

Closures + Anonymity Revisited

```
function greaterThan(bound) {

  return value => value > bound;

}

let testPos = greaterThan(0);
testPos(4)          //=> true
testPos(-3)         //=> false
```

Summary: Coercion, Functions

- Truthy, falsey, and friends
  - Type coercion is everywhere
  - Coerce to boolean in conditionals
  - Coerce to number for ==
- Functions as first-class citizens
  - Can be passed as arguments
  - Can be returned as return values!
  - Closure: carry their context
